

Supplier invoices read into a spreadsheet that checks itself

Okafor Print Co., a made up print shop, gets a folder of supplier PDFs every week. One command turns them into an Excel file and holds back anything it is not sure of.

The problem

Someone retypes supplier invoices every week. Layouts differ by supplier, dates come in three formats, one invoice runs across two pages, and one is a scan with no text. A single wrong figure quietly corrupts the ledger.

What I built

- Extraction of supplier, number, date, every line, net, tax and total
- A split view: the real invoice on the left, what was read on the right, hover to outline its source
- Checks that net plus tax equals the total and the lines add up to the net
- Scans with no text layer sent to a review list instead of guessed
- A styled Excel file with review rows tinted and sorted to the top

Measured results

19 of 20

invoices go straight through, 1 is held for a person

13 tests

including an end to end check of every extracted total

3 bugs

found and fixed, including a 10.30% tax rate being read as an amount

The invoice beside what was read

A value asking to be checked

The Excel output

On the two page invoice, page one shows a running subtotal of \$726.65 and the real net of \$1,070.85 is on page two. The tool uses page two and says so on screen.
